

Dehydration and Hydration

Educational knowledge-base document for an AI Healthcare RAG prototype

What Is Dehydration?

Dehydration occurs when the body loses more fluid than it takes in. Fluid loss can occur through sweating, urination, vomiting, diarrhea, or other processes.

Common Signs

Possible signs of dehydration can include thirst, dry mouth, tiredness, dizziness, and reduced urination. The severity and combination of symptoms can vary.

Reducing Risk

Regular fluid intake can help maintain hydration. During hot weather, exercise, or illness involving fluid loss, fluid needs may change. Individual needs can vary depending on age, activity, environment, and health status.

When to Seek Help

Severe weakness, confusion, fainting, inability to keep fluids down, or other concerning symptoms warrant prompt medical evaluation. Emergency symptoms should be treated as an emergency.

Important Note

This document is for educational and RAG demonstration purposes only. It does not provide individualized medical advice or treatment instructions.
